This manual covers the following areas:

- Introduction
- Discovery API
- Cypher transaction API
- Authentication and authorization

Who should read this?

This manual is written for the developer of a client application which accesses Neo4j through the HTTP API.
Introduction

The Neo4j transactional HTTP endpoint allows you to execute a series of Cypher statements within the scope of a transaction. The transaction may be kept open across multiple HTTP requests, until the client chooses to commit or roll back. Each HTTP request can include a list of statements, and for convenience you can include statements along with a request to begin or commit a transaction.

The server guards against orphaned transactions by using a timeout. If there are no requests for a given transaction within the timeout period, the server will roll it back. You can configure the timeout in the server configuration, by setting Operations Manual → Configuration settings dbms.rest.transaction.idle_timeout to the number of seconds before timeout. The default timeout is 60 seconds.

Responses from the HTTP API can be transmitted as JSON streams, resulting in better performance and lower memory overhead on the server side. To use streaming, supply the header X-Stream: true with each request.

<tbody>
<tr>
<td><strong>💡</strong> In order to speed up queries in repeated scenarios, try not to use literals but replace them with parameters wherever possible. This will let the server cache query plans. See Cypher Manual → Parameters for more information.</td>
<td></td>
</tr>
</tbody>
</table>
Discovery API

The HTTP API uses the port 7474 for HTTP and the port 7473 for HTTPS.

See the Operations Manual > Ports for an overview of the Neo4j-specific ports.

Root discovery

Each server provides a root discovery URI that lists a basic index of other URIs, as well as version information.

Example request

GET http://localhost:7474/
Accept: application/json

Example response

200 OK
Content-Type: application/json

{
  "bolt_direct": "bolt://localhost:7687",
  "bolt_routing": "neo4j://localhost:7687",
  "transaction": "http://localhost:7474/db/{databaseName}/tx",
  "neo4j_version": "4.2.0",
  "neo4j_edition": "enterprise"
}
Cypher transaction API

There are several actions that can be performed using the Cypher transaction HTTP endpoint.

Concepts:

- Transaction flow
- Query format
- Result formats

Using the API:

- Begin a transaction
- Run queries inside a transaction
- Keeping transactions alive with an empty statement
- Commit a transaction
- Rollback an open transaction
- Begin and commit a transaction in one request

Additional actions:

- Execute multiple statements
- Include query statistics
- Return results in graph format

Error handling:

- Expired transactions
- Handling errors
- Handling errors in an open transaction

Transaction flow

Cypher transactions are managed over several distinct URIs that are designed to be used in a prescribed pattern. Facilities are provided to carry out the full transaction cycle over a single HTTP request, or over multiple HTTP requests.

The overall flow is illustrated below, with each box representing a separate HTTP request:
Figure 1. Cypher transaction flow

Transaction lifetime

The state of each transaction is maintained on the server on which the transaction began. Transactions expire automatically after a period of inactivity. By default this is 60 seconds.

To keep a transaction alive without submitting new queries, an empty statement list can be posted to the `/tx/{n}` URI.

Query format

All transaction POST requests can accept one or more Cypher queries within the request payload. This enables a large amount of flexibility in how, and when, queries are sent, and can help to reduce the number of individual HTTP requests overall.

The payload is sent as JSON with the following general structure:

```
{
    "statements": [
        {
            "statement": "...",
            "parameters": {...}
        },
        {
            "statement": "...",
            "parameters": {...}
        },
        ...
    ]
}
```
For example:

```
{
   "statements": [
   {
      "statement": "CREATE (n $props) RETURN n",
      "parameters": {
         "props": {
            "name": "My Node"
         }
      }
   },
   {
      "statement": "CREATE (n $props) RETURN n",
      "parameters": {
         "props": {
            "name": "Another Node"
         }
      }
   }
   ]
}
```

Parameters are included as key-value pairs, with each value adopting a type that corresponds to an entry in the mapping table below:

**Table 1. HTTP API parameter type mappings**

<table>
<thead>
<tr>
<th>JSON Type</th>
<th>Cypher Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>null</td>
<td>Null</td>
</tr>
<tr>
<td>boolean</td>
<td>Boolean</td>
</tr>
<tr>
<td>number</td>
<td>Float</td>
</tr>
<tr>
<td>string</td>
<td>String</td>
</tr>
<tr>
<td>array</td>
<td>List</td>
</tr>
<tr>
<td>object</td>
<td>Map</td>
</tr>
</tbody>
</table>

**Result formats**

**Default**

This format returns JSON with an embedded `results` element. To request this format, place `application/json` in the `Accept` header. This format is the default returned if no `Accept` header is provided.
For example, running the query `UNWIND range(0, 2, 1) AS number RETURN number` will return the following results:

```
{
  "results": [
    {
      "columns": [],
      "data": [
        {
          "row": [row-data],
          "meta": [metadata]
        },
        {
          "row": [row-data],
          "meta": [metadata]
        },
        {
          "row": [row-data],
          "meta": [metadata]
        }
      ]
    },
    {
      // another statement's results
    }
  ]
}
```

Jolt

Jolt, short for JSON Bolt, is a JSON-based format which encloses the response value’s type together with the value inside a singleton object.

For example:
This labels the value 2 as an integer type.

This format can be returned when adding application/vnd.neo4j.jolt to the request’s Accept header.

Line delimited and Sequenced

Jolt may be returned in either line feed delimited or JSON sequence\(^\[1\]\) mode. The formats are made available via the application/vnd.neo4j.jolt and application/vnd.neo4j.jolt+json-seq types which may be passed to the request’s Accept header respectively.

Strict and sparse

There are two modes of Jolt that can be returned:

- **Strict mode**, where all values are paired with their type.
- **Sparse mode**, which omits typing pairing on values which can suitably be matched to JSON types.

By default, the sparse mode is returned. To enable strict mode, pass application/vnd.neo4j.jolt;strict=true or application/vnd.neo4j.jolt+json-seq;strict=true in the Accept header.

Jolt types

Base types

<table>
<thead>
<tr>
<th>Type Label</th>
<th>Type</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>(N/A)</td>
<td>null</td>
<td>null</td>
</tr>
<tr>
<td>?</td>
<td>Boolean</td>
<td>{&quot;?&quot;: &quot;true&quot;}</td>
</tr>
<tr>
<td>Z</td>
<td>Integer</td>
<td>{&quot;Z&quot;: &quot;123&quot;}</td>
</tr>
<tr>
<td>R</td>
<td>Float/Real</td>
<td>{&quot;R&quot;: &quot;9.87&quot;} [1]</td>
</tr>
<tr>
<td>U</td>
<td>String</td>
<td>{&quot;U&quot;: &quot;A string&quot;}</td>
</tr>
<tr>
<td>T</td>
<td>Date/Time</td>
<td>{&quot;T&quot;: &quot;2002-04-16T12:34:56&quot;}</td>
</tr>
<tr>
<td>@</td>
<td>Geospatial</td>
<td>{&quot;@&quot;: &quot;POINT (30 10)&quot;}</td>
</tr>
<tr>
<td>Type Label</td>
<td>Type</td>
<td>Example</td>
</tr>
<tr>
<td>------------</td>
<td>--------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>#</td>
<td>Hexadecimal</td>
<td>{&quot;#&quot;: &quot;FA08&quot;}</td>
</tr>
</tbody>
</table>

### Composite types

<table>
<thead>
<tr>
<th>Type Label</th>
<th>Type</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>[]</td>
<td>List</td>
<td>{&quot;[]&quot;: [{&quot;Z&quot;: &quot;123&quot;}, ...]}</td>
</tr>
<tr>
<td>{}</td>
<td>Dictionary</td>
<td>{&quot;{}&quot;: {&quot;name&quot;: {&quot;U&quot;: &quot;Jeff&quot;}, ...}}</td>
</tr>
</tbody>
</table>

### Entity types

**Node**

```
{"(): [node_id, [ node_labels], {"prop1": "value1", "prop2": "value2"}]}
```

For example:

```
{"(): [4711, ["A", "B"],
    {"prop1": {
        "Z": "1"
    },
    "prop2": {
        "U": "Hello"
    }}]
}
```

**Relationships**

```
{"->": [rel_id, start_node_id, rel_type, end_node_id, {properties}]}
{"<-": [rel_id, end_node_id, rel_type, start_node_id, {properties}]}
```

For example:
Paths

```
{ "..": [{node_1}, {rel_1}, {node_2}, ..., {node_n}, {rel_n}, {node_n+1}]
```

For example:

```
{
  "..": [
    {
      "()": [
        111,
        [],
        {}
      ],
    },
    {
      "->": [
        9090,
        111,
        "KNOWS",
        222,
        {
          "since": {
            "Z": "1999"
          }
        }
      ],
    },
    {
      "()": [
        222,
        [],
        {}
      ]
    }
  ]
}
```

Container format

Jolt results will be returned in a new container format based on events. A typical response will contain:

```
{ "header": { "fields": [ "name", "age" ] } 
 { "data": [ { "U": "Bob", "Z": "30" } ] } 
 { "data": [ { "U": "Alice", "Z": "40" } ] } 
 { "data": [ { "U": "Eve", "Z": "50" } ] } 
 ... 
 { "summary": {} } 
 { "info": { "commit": "commit/uri/1" } }
```
Each event is a separate JSON document separated by a single LF character (Line Feed, UTF encoding: \x8A) or, if JSON sequences are requested, encapsulated within an RS character[^4] (Information Separator Two, UTF-8 encoding: \x1E) at the beginning of each document as well as a LF character at the end:

<table>
<thead>
<tr>
<th>Event</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>header</td>
<td>Marks the start of a result set for a statement, and contains query fields.</td>
</tr>
<tr>
<td>data</td>
<td>For each record returned in the result set there will be a data json object. Depending on the query, each query can return multiple data objects. The order of values in the array match the fields received in the header.</td>
</tr>
<tr>
<td>summary</td>
<td>Marks the end of a result set for a statement. Can contain query plan information if requested.</td>
</tr>
<tr>
<td>info</td>
<td>Final event to appear after processing all statements (unless an error has occurred), and can contain transaction information (e.g. a commit URI).</td>
</tr>
<tr>
<td>error</td>
<td>Errors which occur during the processing of the transaction.</td>
</tr>
</tbody>
</table>

For example, the default Jolt encoding will result in a stream encoded as follows:

```
{"header":{"fields":["result"]}}
{"data":[{"Z":"1"}]}
{"summary":{}}
{"info":{}}
```

While the JSON sequence based Jolt encoding will result in the following response:

```
\001E{"header":{"fields":["result"]}}
\001E{"data":[{"Z":"1"}]}
\001E{"summary":{}}
\001E{"info":{}}
```

Multiple result sets in a request

When there are multiple queries in a single request there will be multiple header, data, and summary outputs for each query.

For example, posting the following request:

```
{"header":{"fields":["result"]}}
{"data":[{"A":"1"},{"Z":"1"}]}
{"summary":{}}
{"info":{}}
```

[^4]: Information Separator Two. UTF-8 encoding: \x1E
will yield the following result response:

{ "header": {"fields": ["resultA"]},  
"data": [ { "Z": "1" } ],  
"summary": {},  
"info": {} }  
{ "header": {"fields": ["resultB"]},  
"data": [ { "Z": "1" }, { "Z": "2" }, { "Z": "3" } ],  
"summary": {},  
"info": {} }

Results sets will be returned in the same order as passed in the original request.

**Begin a transaction**

A new transaction can be started by posting zero or more Cypher queries to the transaction endpoint. The server will respond with the results of your queries, as well as the location of your new transaction.

Transactions expire automatically after a period of inactivity (i.e. queries and a commit). By default this is 60 seconds.

To keep a transaction alive without submitting new queries, an empty statement list can be posted to the transaction URI.

**Example request**

- POST http://localhost:7474/db/neo4j/tx
- Accept: application/json;charset=UTF-8
- Content-Type: application/json

```json
{  "statements": [ {   "statement": "CREATE (n $props) RETURN n",   "parameters": {     "props": {       "name": "My Node"     }   }  } ]}
```

**Example response**

- 201: Created
- Content-Type: application/json;charset=utf-8
- Location: http://localhost:7474/db/neo4j/tx/16
Run queries inside a transaction

Once you have an open transaction by calling `db/{name}/tx`, you can run additional statements that form part of your transaction by calling the newly created transaction endpoint. The endpoint will be in the form `db/{name}/tx/{txid}`, where `txid` is provided in the response of the initial call to begin the transaction.

Example request

- POST http://localhost:7474/db/neo4j/tx/18
- Accept: application/json;charset=UTF-8
- Content-Type: application/json

```json
{
  "statements": [
    {
      "statement": "CREATE (n) RETURN n"
    }
  ]
}
```

Example response

- 200: OK
- Content-Type: application/json;charset=utf-8
Keeping transactions alive with an empty statement

If you need to extend the timeout while processing a transaction, you can send a POST to the transaction’s endpoint with a blank HTTP body.

Example request

- POST http://localhost:7474/db/neo4j/tx/2
- Accept: application/json;charset=UTF-8
- Content-Type: application/json

```json
{
  "statements": []
}
```

Example response

- 200: OK
- Content-Type: application/json;charset=utf-8

```json
{
  "results": [],
  "errors": [],
  "commit": "http://localhost:7474/db/neo4j/tx/2/commit",
  "transaction": {
    "expires": "Mon, 20 Sep 2021 07:57:36 GMT"
  }
}
```

Commit a transaction

When you have executed all the statements for the transaction, and want to commit the changes to the database, you can use POST db/{name}/tx/{txid}/commit, which can also include any final statements to execute before committing.

Example request
**POST** http://localhost:7474/db/neo4j/tx/2/commit

**Accept:** application/json; charset=UTF-8

**Content-Type:** application/json

```json
{
  "statements": [
    {
      "statement": "MATCH (n) WHERE id(n) = $nodeId RETURN n",
      "parameters": {
        "nodeId": 6
      }
    }
  ]
}
```

**Example response**

- **200:** OK
- **Content-Type:** application/json; charset=utf-8

```json
{
  "results": [
    {
      "columns": ["n"],
      "data": [
        {
          "row": [],
          "meta": [
            {
              "id": 6,
              "type": "node",
              "deleted": false
            }
          ]
        }
      ]
    }
  ],
  "errors": []
}
```

**Rollback an open transaction**

Given that you have an open transaction, you can send a rollback request. The server will roll back the transaction. Any attempt to run additional statements in this transaction will fail immediately.

**Example request**

- **DELETE** http://localhost:7474/db/neo4j/tx/3
- **Accept:** application/json; charset=UTF-8

**Example response**

- **200:** OK
- **Content-Type:** application/json; charset=utf-8

```json
{
  "results": [],
  "errors": []
}
```
Begin and commit a transaction in one request

Begin and commit request

If there is no need to keep a transaction open across multiple HTTP requests, you can begin a transaction, execute statements, and commit within a single HTTP request.

Example request

- POST http://localhost:7474/db/neo4j/tx/commit
- Accept: application/json;charset=UTF-8
- Content-Type: application/json

```json
{
  "statements": [
    {
      "statement": "MATCH (n) WHERE id(n) = $nodeId RETURN n",
      "parameters": {
        "nodeId": 7
      }
    }
  ]
}
```

Example response

- 200: OK
- Content-Type: application/json;charset=utf-8

```json
{
  "results": [{
    "columns": ["n"],
    "data": [{
      "row": [{}],
      "meta": [{
        "id": 7,
        "type": "node",
        "deleted": false
      }]
    }
  }],
  "errors": []
}
```

Legacy Endpoints  

The API described in this section of the manual has been deprecated and will be removed in Neo4j 5.0.

Example request

- POST http://localhost:7474/db/neo4j/tx/commit
- Accept: application/json;charset=UTF-8
Example response

- 200: OK
- Content-Type: application/json;charset=utf-8

```json
{
  "results": [
    {
      "columns": ["n"],
      "data": [
        {
          "row": [],
          "meta": [
            {
              "id": 2,
              "type": "node",
              "deleted": false
            }
          ]
        }
      ]
    }
  ],
  "errors": []
}
```

Execute multiple statements

It is possible to send multiple Cypher statements in the same request. The response will contain the result of each statement.

Example request

- POST http://localhost:7474/db/neo4j/tx/commit
- Accept: application/json;charset=UTF-8
- Content-Type: application/json

```json
{
  "statements": [
    {
      "statement": "RETURN 1"
    },
    {
      "statement": "RETURN 2"
    }
  ]
}
```

Example response

- 200: OK
Include query statistics

By setting `includeStats` to `true` for a statement, query statistics will be returned for it.

Example request

- **POST** http://localhost:7474/db/neo4j/tx/commit
- **Accept:** application/json;charset=UTF-8
- **Content-Type:** application/json

```
{
  "statements": [
    {
      "statement": "CREATE (n) RETURN id(n)",
      "includeStats": true
    }
  ]
}
```

Example response

- **200:** OK
- **Content-Type:** application/json; charset=utf-8
Return results in graph format

If you want to understand the graph structure of nodes and relationships returned by your query, you can specify the graph results data format. This is useful when you want to visualize the graph structure. The format collates all the nodes and relationships from all columns of the result, and also flattens collections of nodes and relationships, including paths.

Example request

- POST http://localhost:7474/db/neo4j/tx/commit
- Accept: application/json;charset=UTF-8
- Content-Type: application/json

```json
{
  "statements": [
    {
      "statement": "CREATE (bike:Bike {weight: 10}) CREATE (frontWheel:Wheel {spokes: 3}) CREATE (backWheel:Wheel {spokes: 32}) CREATE p1 = (bike)-[:HAS {position: 1}]->(frontWheel) CREATE p2 = (bike)-[:HAS {position: 2}]->(backWheel) RETURN bike, p1, p2",
      "resultDataContents": ["row", "graph"]
    }
  ]
}
```

Example response

- 200: OK
- Content-Type: application/json;charset=utf-8

```json
{
  "results": [
    {
      "columns": ["bike", "p1", "p2"],
      "data": [null, null, null]
    }
  ]
}
```
Expired transactions

If an attempt is made to commit a transaction which has timed out, you will see the following error:

```
404 Not Found
Content-Type: application/json
{
    "results": [],
    "errors": [
        {
            "code": "Neo.ClientError.Transaction.TransactionNotFound",
            "message": "Unrecognized transaction id. Transaction may have timed out and been rolled back."
        }
    ]
}
```

Handling errors

The result of any request against the transaction endpoint is streamed back to the client. Therefore, the server does not know whether the request will be successful or not when it sends the HTTP status code.

Because of this, all requests against the transactional endpoint will return 200 or 201 status code, regardless of whether statements were successfully executed. At the end of the response payload, the server includes a list of errors that occurred while executing statements. If the list is empty, the request completed successfully.

If errors occur while executing statements, the server will roll back the transaction.

In this example, we send an invalid statement to the server in order to demonstrate error handling.

For more information on the status codes, see Neo4j Status Codes.

Example request

- POST http://localhost:7474/db/neo4j/tx/17/commit
- Accept: application/json;charset=UTF-8
- Content-Type: application/json

```
{
    "statements": [
        {
            "statement": "This is not a valid Cypher Statement."
        }
    ]
}
```
Handling errors in an open transaction

If there is an error in a request, the server will roll back the transaction. You can tell if the transaction is still open by inspecting the response for the presence/absence of the `transaction` key.

Example request

- POST http://localhost:7474/db/neo4j/tx/15
- Accept: application/json;charset=UTF-8
- Content-Type: application/json

```
{
  "statements": [
    {
      "statement": "This is not a valid Cypher Statement."
    }
  ]
}
```

Example response

- 200: OK
- Content-Type: application/json;charset=utf-8

```
{
  "results": [ ],
  "errors": [ {
    "code": "Neo.ClientError.Statement.SyntaxError",
    "message": "Invalid input 'T': expected <init> (line 1, column 1 (offset: 0))\n"This is not a valid Cypher Statement.\n"
  } ],
  "commit": "http://localhost:7474/db/neo4j/tx/15/commit"
}
```

[1] JSON Sequences are encoded as outlined in RFC 7464.
[2] The type label `R` is used both to indicate floating point numbers and integers that are outside the range of 32-bit signed integers.
[3] The common name is Record Separator, and the Unicode name is Information Separator Two.
Authentication and authorization

Authentication and authorization are enabled by default in Neo4j (refer to Operations Manual → Authentication and authorization). With authentication and authorization enabled, requests to the HTTP API must be authorized using the username and password of a valid user.

Missing authorization

If an Authorization header is not supplied, the server will reply with an error.

Example request

- POST http://localhost:7474/db/neo4j/tx/commit
- Accept: application/json;charset=UTF-8
- Content-Type: application/json

```
{
  "statements": [
    {
      "statement": "CREATE (n:MyLabel) RETURN n"
    }
  ]
}
```

Example response

- 401: Unauthorized
- Content-Type: application/json;charset=utf-8
- WWW-Authenticate: Basic realm="Neo4j"

```
{
  "errors" : [ {
    "message" : "No authentication header supplied."
  } ]
}
```

If authentication and authorization have been disabled, HTTP API requests can be sent without an Authorization header.

Incorrect authentication

If an incorrect username or password is provided, the server replies with an error.

Example request

- POST http://localhost:7474/db/neo4j/tx/commit
- Accept: application/json;charset=UTF-8
• Authorization: Basic bmVvNGo6aW5jb3JyZWN0
• Content-Type: application/json

```json
{
   "statements": [
      {
         "statement": "CREATE (n:MyLabel) RETURN n"
      }
   ]
}
```

Example response

• 401: Unauthorized
• Content-Type: application/json;charset=utf-8
• WWW-Authenticate: Basic realm="Neo4j"

```
{
   "errors" : [ {
      "message" : "Invalid username or password."
   } ]
}
```

Authentication failure on open transactions

A Neo.ClientError.Security.Unauthorized error will typically imply a transaction rollback. However, due to the way authentication is processed in the HTTP server, the transaction will remain open.
